Abstract

Multiplication layers are a key component in various influential neural network modules, including self-attention and hypernetwork layers. In this paper, we investigate the approximation capabilities of deep neural networks with intermediate neurons connected by simple multiplication operations. We consider two classes of target functions: generalized bandlimited functions, which are frequently used to model real-world signals with finite bandwidth, and Sobolev-Type balls, which are embedded in the Sobolev Space $\mathcal{W}^{r,2}$. Our results demonstrate that multiplicative neural networks can approximate these functions with significantly fewer layers and neurons compared to standard ReLU neural networks, with respect to both input dimension and approximation error. These findings suggest that multiplicative gates can outperform standard fully-connected layers and potentially improve neural network design.

1   Introduction

Deep learning with large neural networks has seen tremendous success in solving a wide range of tasks in recent years, including image classification (He et al., 2016; Dosovitskiy et al., 2021; Zhai et al., 2021), language processing (Vaswani et al., 2017; Devlin et al., 2019; Brown et al., 2020), interacting with open-ended environments (Silver et al., 2016; Arulkumaran et al., 2019), and code synthesis (Chen et al., 2021).

Recent empirical studies have shown that neural networks that incorporate multiplication operations between intermediate neurons (Durbin & Rumelhart, 1989; Urban & van der Smagt, 2015; Trask et al., 2018), such as self-attention layers (Vaswani et al., 2017), dynamic convolutions (Wu et al., 2019) and hypernetworks (Ha et al., 2016; Krueger et al., 2017; Littwin & Wolf, 2019), are particularly effective. For example, self-attention layers have been widely successful in computer vision (Dosovitskiy et al., 2021; Zhai et al., 2021) and language processing (Cheng et al., 2016; Parikh et al., 2016; Paulus et al., 2017; Vaswani et al., 2017). It has also been shown that one can achieve reasonable performance with Transformers even without applying non-linear activation functions (Levine et al., 2020). Additionally, hypernetworks, which use multiplication to generate network weights seem to improve the performance of neural networks on various meta-learning tasks (von Oswald et al., 2020; Littwin & Wolf, 2019; Bensadoun et al., 2021). In a different line of work, Haber & Ruthotto (2018); Eliasof et al. (2021) showed that incorporating non-linear interactions can stabilize the training of deep networks, including convolutional and graph neural networks. Despite their practical success, the theoretical reasons behind the effectiveness of multiplicative layers in deep learning remain unclear.

In this work, we study the expressive power of neural networks with multiplication layers. Specifically, we want to evaluate the number of neurons and layers needed to approximate a given function within a given error tolerance using a specific architecture. A classic result in the theory of deep learning shows that neural networks can approximate any smooth target function, known as the universal approximation property, with as few as one hidden layer (Cybenko, 1989; Hornik et al., 1989; ichi Funahashi, 1989; Leshno et al., 1991). However, these papers do not provide specific information about the type of architecture and number of parameters required to achieve a given level of accuracy. This is a crucial question, as a high requirement for these resources could limit the universality of neural networks and explain their limited success in some practical applications.

In a recent paper, Jayakumar et al. (2020) investigated the role of multiplicative interaction as a framework including various classical and contemporary neural network components, including gating, attention layers, hypernetworks, and dynamic convolutions. The authors conjectured that multiplicative layers are well-suited for modeling conditional computations and proved that networks with multiplicative connections are more expressive than those with ReLU fully-connected layers. However, they did not investigate to what extent the multiplicative networks serve as better function approximators than standard ReLU networks.

Previous work has demonstrated that functions in Sobolev spaces can be approximated by a one-hidden layer neural network with analytic activation functions (Mhaskar, 1996). However, the number of neurons required to approximate these functions with an error of at most ϵ in the L_∞ norm scales as $\mathcal{O}(\epsilon^{-d/r})$, where d is the input dimension, r is the smoothness degree of the target function, and $\epsilon > 0$ is the error rate. This raises the question of whether the curse of dimensionality, the phenomenon whereby the complexity of a model grows exponentially with the input dimension, is inherent to neural networks.

On the other hand, DeVore et al. (1989) proved that any continuous function approximator that approximates all Sobolev functions of order r and dimension d within error ϵ requires at least $\Omega(\epsilon^{-d/r})$ parameters in the L_∞ norm. This result meets the bound of Mhaskar (1996) and confirms that neural networks cannot avoid the curse of dimensionality for the Sobolev space when approximating in the L_∞ norm. A key question is whether neural networks can overcome this curse of dimensionality for certain sets of target functions, and what kind of architectures provide the best guarantees for approximating these functions.

To overcome the curse of dimensionality, various studies (Mhaskar et al., 2017; Poggio et al., 2020; Kohler & Krzyżak, 2017; Montanelli & Du, 2019; Blanchard & Bennouna, 2022b; Galanti & Wolf, 2020) have investigated the approximation capabilities of neural networks in representing other classes of functions with weaker notions of distance, such as the L_2 distance. For example, Mhaskar et al. (2017); Poggio et al. (2020) showed that smooth, compositionally sparse functions with a degree of smoothness r can be approximated with the L_∞ distance up to error ϵ using deep neural networks with $\mathcal{O}(d\epsilon^{-2/r})$ neurons. Other structural constraints have been applied to functions with structured input spaces (Mhaskar, 2010; Nakada & Imaizumi, 2022; Schmidt-Hieber, 2019b), compositions of functions (Kohler & Krzyżak, 2017), piecewise smooth functions (Petersen & Voigtländer, 2017; Imaizumi & Fukumizu, 2018). A different line of research has focused on understanding the types of functions that certain neural network architectures can implement with regularity constraints. For example, E et al. (2021) showed that the space of 2-layer neural networks is equivalent to the Barron space when the size of their weights is restricted. They further showed that Barron functions can be approximated within ϵ using 2-layer networks with $\mathcal{O}(\epsilon^{-2})$ neurons. Another line of research has considered spectral conditions on the function space, allowing functions to be expressed as infinite-width limits of shallow networks (Barron, 1991; Klusowski & Barron, 2016). In (Blanchard & Bennouna, 2022b) they considered the space of Korobov functions, which are functions that are practically useful for solving partial differential equations (PDEs). They showed any Korobov function can be approximated up to error ϵ in L_2 distance with a 2-layer neural network with ReLU activation function with $\mathcal{O}(\epsilon^{-1}\log(1/\epsilon)^{1.5(d-1)+1})$ and with a $\mathcal{O}(\log(d))$-depth network with $\mathcal{O}(\epsilon^{-0.5}\log(1/\epsilon)^{1.5(d-1)+1})$ neurons.

It is generally known that real-world datasets (such as CIFAR10 or ImageNet) often (approximately) lie on low-dimensional manifolds of the input space (Tenenbaum et al., 2000; Belkin & Niyogi, 2003). Several publications (Nakada & Imaizumi, 2019; Schmidt-Hieber, 2019a; Chen et al., 2019; Kohler et al., 2019; Suzuki, 2018) studied the adaptivity of deep ReLU networks to the intrinsic dimensionality of data and in particular showed that the curse of dimensionality is avoidable when the data lies on a low-dimensional manifold. The work of (Suzuki & Nitanda, 2019) further showed that deep ReLU networks can overcome the curse of dimensionality even when the input data does not lie on a low-dimensional manifold, as long as the target function is included in some anisotropic Besov space Danskin & Nikol'skii (2012). In (Shen et al., 2021) the authors showed that general target function classes (such as the Hölder or Lipschitz spaces) may be modeled by a single network, of a certain architecture, such that only a small number of 'intrinsic' parameters are used to approximate each individual function.

In a recent paper, Montanelli et al. (2021) provided approximation guarantees were established for generalized bandlimited functions. These functions are commonly used to model signals that have a finite range of frequencies (e.g., waves, video, and audio signals), which is known as a finite bandwidth. The solutions to many

PDEs in physics are bandlimited functions, as the physical phenomena modeled by these PDEs typically have a finite range of frequencies. For example, the solutions to the wave equation, which models the propagation of waves, are bandlimited functions. In (Montanelli et al., 2021), it was shown that any bandlimited function can be approximated to within error ϵ using a ReLU neural network of depth $\mathcal{O}(\log^2(1/\epsilon))$ with $\mathcal{O}(\epsilon^{-2}\log^2(1/\epsilon))$ neurons with the L_2 distance.

In this paper, we compare the approximation capabilities of multiplicative neural network architectures with those of standard ReLU networks with respect to the L_2 distance. In particular, we prove that a multiplicative neural network of depth $\mathcal{O}(\log(\frac{1}{\epsilon}))$ with $\mathcal{O}(\epsilon^{-2}\log(\frac{1}{\epsilon}))$ neurons can approximate any generalized bandlimited function up to an error of ϵ (with constants depending on the dimension and on the band). This result represents an improvement compared to the findings in (Montanelli et al., 2021) for traditional ReLU networks. Additionally, we also study the approximation guarantees of neural networks for approximating functions in Sobolev-Type balls of order r. We show that for the same error tolerance ϵ, multiplicative neural networks can approximate these functions with depth $\mathcal{O}(d\epsilon^{-1/r})$ and $\mathcal{O}(d\epsilon^{-(2+1/r)})$ neurons, while standard ReLU neural networks require depth $\mathcal{O}(d^2\epsilon^{-2/r})$ and $\mathcal{O}(d^2\epsilon^{-(2+2/r)})$ neurons. These results demonstrate the superior performance of multiplicative gates compared to standard fully-connected layers. In Table 1 we contrast our new bounds with preexisting bounds on the approximation power of neural networks for the Sobolev space, bandlimited functions, and the Sobolev-Type ball.

Table 1: Approximation results for Sobolev $\mathcal{W}^{r,p}$, Bandlimited and $\mathcal{B}_{2r,2}$ functions by ReLU and multiplicative neural networks. The number of neurons and the depth are given in $\mathcal{O}$ notation.

2 Problem Setup

We are interested in determining how complex (i.e., number of trainable parameters, number of neurons and layers) a model ought to be in order to theoretically guarantee approximation of an unknown target function f up to a given approximation error $\epsilon > 0$.

Formally, we consider a Banach space of functions $\mathcal{V}$ (for example, $L_p([0,1]^d)$), equipped with a norm $\|\cdot\|_{\mathcal{V}}$ (for example, $\|\cdot\|_{L_p([0,1]^d)}$), and a set of target functions $\mathcal{U} \subseteq \mathcal{V}$. We also consider a set of approximators $\mathcal{H}$ and seek to quantify the ability of these approximators to approximate $\mathcal{U}$ using the following quantity

$$d_{\mathcal{V}}(\mathcal{H},\mathcal{U}) \;=\; \sup_{f\in\mathcal{U}}\inf_{\hat{f}\in\mathcal{H}}\|\hat{f}-f\|_{\mathcal{V}},$$

which measures the maximal approximation error for approximating a target function $f \in \mathcal{U}$ using candidates $\hat{f}$ from $\mathcal{H}$. Typically, $\mathcal{H}$ is a parametric set of functions (e.g., neural networks of a certain architecture) and we denote by $\hat{f}_\theta \in \mathcal{H}$ a function that is parameterized by a vector of parameters $\theta \in \mathbb{R}^N$. For simplicity, we avoid writing θ in the subscript when it is obvious from context.

2.1 Target Function Spaces

It is generally impossible to approximate arbitrary target functions using standard neural networks, as demonstrated in Theorem 7.2 in (Devroye et al., 1996). As a result, we often consider specific spaces of target functions that satisfy certain smoothness assumptions in order to obtain non-trivial results. In this work,

we focus specifically on target functions $\mathcal{U}$ over the unit cube $B = [0, 1]^d$ that satisfy the following types of smoothness assumptions.

Sobolev spaces. Sobolev spaces are one of the most extensively studied classes of functions in approximation theory (DeVore & Lorentz, 1993; Yarotsky, 2017; Liang & Srikant, 2017). These spaces consist of smooth functions with bounded derivatives up to a certain order and are particularly useful in the study of partial differential equations (PDEs).

We first define the L_p norm of a given function $f : \Omega \to \mathbb{R}$ as $\|f\|_{L_p(\Omega)} = (\int_\Omega |f(x)|^p \ dx)^{1/p}$, where Ω is a measurable space equipped with a Sigma-algebra Σ and a measure μ. A function f is said to be in $L_p(\Omega)$ if $\|f\|_{L_p(\Omega)} < \infty$.

Let $r \in \mathbb{N}$ and $p \in [1, \infty)$. The Sobolev space $\mathcal{W}^{r,p}(B)$ consists of functions $f : B \to \mathbb{R}$ with r-distributional derivatives in L_p. The Sobolev norm $\|\cdot\|_{\mathcal{W}^{r,p}(B)}$ is defined as

$$\|f\|_{\mathcal{W}^{r,p}(B)} = \sum_{\alpha:|\alpha|_1 \leq r} \|D^\alpha f\|_{L_p(B)},$$

where $\alpha = (\alpha_1, \ldots, \alpha_d) \in \{0, \ldots, r\}^d, |\alpha|_1 = \alpha_1 + \cdots + \alpha_d$, and $D^\alpha f$ is the respective distributional derivative. When $p = \infty$, the essential supremum norm is used. We also present the semi-norm:

$$|f|_{r,p} = \sum_{\alpha \ : \ |\alpha|=r} \|D^\alpha f(x)\|_{L_p(B)}.$$

Classic results in the literature show that the number of parameters needed to approximate functions in $\mathcal{W}^{r,\infty}$ up to error ϵ is lower bounded by $\Omega(\epsilon^{-d/r})$ (DeVore et al., 1989). This exponential dependence on d is known as the "curse of dimensionality".

Generalized Bandlimited functions. Generalized bandlimited functions are functions whose spectrum, or the set of frequencies that make up the function, is limited to a certain band or range of frequencies. This property makes bandlimited functions well-suited for certain applications, such as signal processing, where it is important to ensure that the signal does not contain frequencies outside of a certain range.

Generalized bandlimited functions are defined using their generalized Fourier transform given by an analytic function $K : \mathbb{R} \to \mathbb{C}$ (known as the kernel) and a scalar $M \geq 1$ (the band). Formally, for a given function $f : \mathbb{R}^d \to \mathbb{R}$, we denote the set of all functions $F : [-M, M]^d \to \mathbb{C}$ that retrieve f from the frequencies $\omega \in [-M, M]^d$ using the kernel K as follows:

$$S_{f,K} = \left\{ F : [-M, M]^d \to \mathbb{R} \mid f(x) = \int_{[-M,M]^d} F(\omega)K(\omega \cdot x) \ d\omega \right\}.$$

We define $F_f = \arg\min_{F \in S_{f,K}} \|F\|_{L^2([-M,M]^d)}$ to be the smallest L_2-norm function in $S_{f,K}$. For instance, when $K(x) = \exp(ix)$, the function F_f corresponds to the normalized standard Fourier transform of f, which is given by $F = \frac{1}{(2\pi)^d}(\mathcal{F}f)(\omega) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} f(x) \exp(-i\omega \cdot x) \ dx$.

The space $\mathcal{H}_{K,M}(B)$ of generalized bandlimited functions is a Hilbert space of functions that can be represented as a weighted sum of the function K over a finite domain. This space is equipped with an inner product and a norm, which allow us to measure the similarity and magnitude of these functions, respectively. We define $\mathcal{H}_{K,M}(B)$ as the functions $f : B \to \mathbb{R}$ such that

$$\mathcal{H}_{K,M}(B) = \left\{ \forall x \in B, f(x) = \int_{[-M,M]^d} F(\omega)K(\omega \cdot x) \ d\omega \mid F : [-M, M]^d \to \mathbb{C} \text{ is in } L^2([-M, M]^d) \right\}.$$

The inner product and norm in this space are defined as follows: $\langle f, g \rangle_{\mathcal{H}_{K,M}(B)} = \int_{[-M,M]^d} F_f(\omega)\overline{F_g}(\omega) \ d\omega$ and norm $\|f\|_{\mathcal{H}_{K,M}(B)} = \|F_f\|_{L^2([-M,M]^d)}$.

One of the key properties of generalized bandlimited functions is that they can be completely reconstructed from a discrete set of samples. This is known as the Shannon-Nyquist theorem (Shannon, 1984), and it is an important result in the field of signal processing and communication. An interesting consequence of this

theorem is that even in high-dimensions, where seemingly unpredictable geometrical phenomena may occur (e.g. Blum et al. (2020), Chapter 2), still perfectly reconstruct a function given it's values at the Nyquist frequency. For more details, see Appendix A.

Sobolev-Type Balls. Sobolev-Type balls are sets of functions that satisfy smoothness constraints on higher-order derivatives (Barron, 1993; Jones, 1992; Pinkus, 1985; Wahba, 1990; Blanchard & Bennouna, 2022a). One such constraint is that the magnitude of the function's Fourier transform, $|\mathcal{F}f(\omega)|$, decays fast enough as $|\omega|$ approaches infinity. These constraints are imposed by comparing the magnitude of the Fourier transform of the function, $\mathcal{F}f(\omega)$, with the magnitude of $|\omega|^r$ for some number $r > 0$. In this paper we define a generalized form of Sobolev-type balls:

$$\mathcal{B}_{r,\rho} = \left\{ f : \mathbb{R}^d \to \mathbb{R}, f \in L_2(\mathbb{R}^d) : \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |(\mathcal{F}f)(\omega)| \ \mathrm{d}\omega, \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |\omega|^r |(\mathcal{F}f)(\omega)|^\rho \ \mathrm{d}\omega \le 1 \right\}.$$

In (Barron, 1993), they explored the ability of neural networks to approximate functions in the space $P_1 = \{f \in L_2(\mathbb{R}^d) \mid \int_{\mathbb{R}^d} |\omega| |(\mathcal{F}f)(\omega)| < \infty\}$. We now demonstrate that any function in P_1 has a normalized representation in $\mathcal{B}_{1,1}$. For this, we show that the conditions on P_1 allow us to bound $\|\mathcal{F}f\|_{L_1(\mathbb{R}^d)}$. Namely,

$$\begin{aligned}
\int_{\mathbb{R}^d} |(\mathcal{F}f)(\omega)| \ \mathrm{d}\omega &= \int_{[-1,1]^d} |(\mathcal{F}f)(\omega)| \ \mathrm{d}\omega + \int_{\mathbb{R}^d \setminus [-1,1]^d} |(\mathcal{F}f)(\omega)| \ \mathrm{d}\omega \\
&\le C_1 \left(\int_{[-1,1]^d} |(\mathcal{F}f)(\omega)|^2 \ \mathrm{d}\omega \right)^{1/2} + \int_{\mathbb{R}^d \setminus [-1,1]^d} |\omega| |(\mathcal{F}f)(\omega)| \ \mathrm{d}\omega \\
&\le C_1 \|f\|_2 + \int_{\mathbb{R}^d} |\omega| |(\mathcal{F}f)(\omega)| \ \mathrm{d}\omega,
\end{aligned}$$

for $C_1 > 0$. Therefore, any function in the space P_1 can be scaled to a function in $\mathcal{B}_{1,1}$. Specifically, they showed that sigmoidal neural networks with a bounded depth and $\mathcal{O}(d\epsilon^{-2})$ neurons can approximate such functions with error at most ϵ.

In this paper we will focus on the space $\mathcal{B}_{2r,2}$. In Lemma 2 (Appendix D) we show that this space is embedded as a proper subspace of $\mathcal{W}^{r,2}$, with the following norm:

$$\|f\|_{\mathcal{B}_{2r,2}} = \left(\frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} (1 + |\omega|^{2r}) |(\mathcal{F}f)(\omega)|^2 \ \mathrm{d}\omega \right)^{1/2}. \tag{1}$$

In Lemma 2 (Appendix D), we also show an example of why the Sobolev space $\mathcal{B}_{2r,2}$ is of particular interest. Specifically, we show that the additional condition that $\mathcal{F}f(\omega) \in L_1$ defines a subspace of $\mathcal{W}^{r,2}$ that can be easily approximated using multiplicative networks. It is worth mentioning that Pinkus (1985) showed that using traditional basis functions, functions of the space $P_2 = \{f \in L_2(\mathbb{R}^d) \mid \int_{\mathbb{R}^d} |\omega|^{2r} |(\mathcal{F}f)(\omega)|^2 < \infty\}$ may be approximated with error at most ϵ using $\mathcal{O}(\epsilon^{-d/2r})$ parameters. In this paper, we show that by enforcing an additional constraint on the L_1 norm of the Fourier coefficients, we can circumvent exponential dependence on the dimension d.

2.2 Neural Network Architectures

In the previous section, we described a setting in which a class of candidate functions $\mathcal{H}$ serve as approximators to a class of target functions $\mathcal{U}$. In this work, we compare the approximation guarantees of standard multilayer perceptrons and a generic set of neural networks that incorporate multiplication operations. Our goal is to understand whether multiplication layers can provide better guarantees to approximate bandlimited functions and members of $\mathcal{B}_{2r,2}$.

Multilayer perceptrons. A multilayer perceptron is a type of neural network architecture that consists of L layers of linear transformations interspersed with element-wise non-linear activation functions (e.g., the ReLU function). Typically, the last layer does not include a non-linear activation.

Definition 1 (Multilayer perceptron). *A multilayer perceptron is a function $f = y_{L,1} : \mathbb{R}^{p_0} \to \mathbb{R}$ defined by a set of univariate functions $\bigcup_{i=0}^{L} \{y_{i,j}\}_{j=1}^{p_i}$. Each function $y_{i,j} : \mathbb{R}^{p_0} \to \mathbb{R}$ (also known as a neuron) is recursively computed in the following manner*

$$
\begin{aligned}
y_{L,j}(x) &= \langle w_{L,j}, y_{L-1}(x) \rangle + b_{L,j} \\
y_{i,j}(x) &= \sigma(\langle w_{i,j}, y_{i-1}(x) \rangle + b_{i,j}) \\
y_{0,j}(x) &= x_j,
\end{aligned}
$$

where $i \in [L-1]$, $j \in [p_i]$, and $w_{i,j} \in \mathbb{R}^{p_{i-1}}$ and $b_{i,j} \in \mathbb{R}$ are the weights and a bias of the neuron $y_{i,j}$ and $y_i = (y_{i,1}, \ldots, y_{i,p_i})$. The function $\sigma : \mathbb{R} \to \mathbb{R}$ is a non-linear activation function.

In this work, we focus on neural networks with ReLU activations, which are defined as $\sigma(x) = \max(0, x)$. However, it is worth noting that other activation functions have been proposed in the literature, such as sigmoidal functions that are measurable functions η that satisfy $\eta(x) \to 0$ as $x \to -\infty$ and $\eta(x) \to 1$ as $x \to \infty$.

Multiplicative neural networks. In this work, we are interested in comparing the approximation abilities of standard ReLU networks, with that of neural networks that incorporate multiplication layers (also known as product units (Durbin & Rumelhart, 1989)). In order to fully understand the added benefits of multiplication gates, we ask the following question: *Are multiplications between neurons sufficient to substitute the non-linear activations in multilayer perceptrons?*

Definition 2 (Multiplicative network). *A multiplicative neural network is a function $f = y_{L,1} : \mathbb{R}^{p_0} \to \mathbb{R}$ defined by a set of univariate functions $\bigcup_{i=1}^{L} \{y_{i,j}\}_{j=1}^{p_i}$. For each neuron, $y_{i,j} : \mathbb{R}^{p_0} \to \mathbb{R}$ there exists a pair of indices $j_1, j_2 \in \{1, \ldots, p_{i-1}\}$ (potentially dependent on i, j) such that $y_{i,j}$ is defined as follows*

$$
\begin{aligned}
y_{i,j}(x) &= \langle w_{i,j}, y_{i-1}(x) \rangle + a_{i,j} y_{i-1,j_1}(x) y_{i-1,j_2}(x) + b_{i,j} \\
y_{0,j}(x) &= x_j,
\end{aligned}
$$

where $a_{i,j}, b_{i,j} \in \mathbb{R}$, $w_{i,j} \in \mathbb{R}^{p_{i-1}}$ are trainable parameters, and $y_i = (y_{i,1}, \ldots, y_{i,p_i})$.

Multiplicative networks differ from multilayer perceptrons as they rely on (non-linear) multiplicative gates between neurons instead of element-wise activation functions, such as ReLU or sigmoid, to model complex functions. Each neuron $y_{i,j}$ is very similar to a standard neuron in a multilayer perceptron, with the distinction that a weighted multiplication between a single pair of neurons y_{i-1,j_1}, y_{i-1,j_2} is added to the output. The total number of trainable parameters in a multiplicative layer is $p_{i+1}p_i + 2p_i$, which is comparable to the $p_{i+1}p_i + p_i$ in a fully-connected layer. Following Yarotsky (2017); Blanchard & Bennouna (2022a) we measure the complexity of a neural network using its depth L and the number of neurons $G = \sum_{i=1}^{L-1} p_i$ it includes.

Self-Attention and multiplicative layers. Let us describe a single-headed self-attention operation in the original Transformer (Vaswani et al., 2017). Each layer $i \in [L]$ of a depth-L Transformer encoder is defined as follows. The input to the ith layer is a sequence of N tokens, denoted by $x_i = \{x_{i,j}\}_{j=1}^{N}$, where each $x_{i,j} \in \mathbb{R}^{d_x}$ represents the jth token of the ith layer. To compute the output of the ith layer at a particular position $e \in [N]$, we use the following formula:

$$
f_{\text{SA}}^{i,e}(x_i) = \sum_{j=1}^{N} \text{softmax}_j \left(\frac{1}{\sqrt{d_a}} \langle W^{Q,i} x_{i,e}, W^{K,i} x_{i,e} \rangle \right) W^{V,i} x_{i,j},
$$

where $\text{softmax}_j(f(x)) = \exp(f(x)_j)/\sum_{j'} \exp(f(x)_{j'})$ is the softmax operator, and the trainable weight matrices $W^{K,i}$, $W^{Q,i}$, $W^{V,i} \in \mathbb{R}^{d_a \times d_x}$ convert the representation from its dimension d_x into the attention dimension $d_a = d_x$, creating 'Key', 'Query', and 'Value' representations, resp. As can be seen, the self-attention layers use multiplicative connections when computing the following inner product $\langle W^{Q,i} x_{i,e}, W^{K,i} x_{i,e} \rangle$. This operation computes multiplications between the coordinates of transformations of the same token $x_{i,e}$. In other words, it can be thought of as computing a multiplicative layer on an input vector $x_{i,e}$. As a side note, in addition to self-attention layers, transformers also incorporate commonly used layers such as fully-connected layers, residual connections, and normalization layers, which are not the focus of this paper.

3 Representation Power of Multiplicative Neural Networks

In this section, we explore the expressive power of neural networks with multiplication layers. We first demonstrate that these networks can easily represent polynomial functions, which we then use to approximate bandlimited functions. This allows us to approximate functions in the space $\mathcal{B}_{2r,2}$ without suffering from the curse of dimensionality. Specifically, we prove the following lemma:

Lemma 1. *For any polynomial $p_n : \mathbb{R} \to \mathbb{R}$ of degree n of the form $p_n(x) = \sum_{k=0}^{n} c_k x^k$, there exists a multiplicative neural network $f_n^{\text{POL}} : \mathbb{R}^3 \to \mathbb{R}$, of depth $L_n = \mathcal{O}(n)$ with $G_n = \mathcal{O}(n)$ neurons that satisfies $f_n^{\text{POL}}(x, x, c_0) = p_n(x)$ for $c_0 \in \mathbb{R}$, and $x \in \mathbb{R}$.*

The above lemma shows how to use multiplicative networks to approximate analytic kernel functions $K : \mathbb{R} \to \mathbb{C}$ by leveraging their ability to represent polynomials. By approximating a certain class of polynomials, we demonstrate how to use these networks to approximate analytic kernels. Once we have the ability to approximate analytic kernels, we can use Maurey's Theorem (see Lemma 3) to express any function $f \in \mathcal{H}_M$ as a finite sum of kernel superpositions, and construct a network that approximates this sum.

Approximating of real-valued analytic functions. In this section, we show how to approximate certain real-valued analytic functions. For this purpose, we recall the notion of the Bernstein s-ellipse, which is a geometric shape defined on the complex plane that is useful in approximation theory.

Definition 3. *Let $M > 0$, $s > 1$ be two scalars. The Bernstein s-ellipse on $[-M, M]$ is defined as follows*

$$E_s^M = \left\{ x + iy \in \mathbb{C} : \frac{x^2}{(a_s^M)^2} + \frac{y^2}{(b_s^M)^2} = 1 \right\},$$

whose semi-major and semi-minor axes are $a_s^M = M \frac{s + s^{-1}}{2}$ and $b_s^M = M \frac{s - s^{-1}}{2}$.

The parameter s controls the shape of the ellipse, and the parameter M determines its size. As s increases, the ellipse converges to a circle. The semi-major and semi-minor axes of the ellipse determine its maximal and minimal values, respectively. Before stating our result in Theorem 2, we recall the following theorem of Trefethen (2019):

Theorem 1 (Theorem 8.2 of Trefethen (2019)). *Let $M > 0, s > 2$ be scalars and $K : [-M, M] \to \mathbb{R}$ be an analytic function that is analytically continuable to the ellipse E_s^M, where it satisfies $\sup_{x \in E_s^M} |K(x)| \leq C_K$ for some constant $C_K > 0$. For every $n \in \mathbb{N}$, there exists a polynomial $h_n : \mathbb{R} \to \mathbb{C}$ of degree n, such that,*

$$\|h_n - K\|_{L^\infty([-M,M])} \leq \frac{2 C_K s^{-n}}{s - 1}.$$

Theorem 1 states that any analytic function K that is bounded on the Bernstein s-ellipse E_s^M can be accurately approximated by a polynomial h_n of degree n, with the error decreasing exponentially as the degree n increases.

As we show next, the use of multiplication layers in neural networks can improve the efficiency of function approximation in certain cases. The following theorem shows that deep multiplicative networks can approximate real-valued analytic functions on bounded intervals.

Theorem 2. *Let $M \geq 1$, $s > 2$, $C_K > 0$ and $\epsilon \in (0, 1)$ be scalars. Then, for any real-valued analytic function $K : [-M, M] \to \mathbb{R}$ that is analytically continuable to the ellipse E_s^M where $|K(x)| \leq C_K$, there exists a deep multiplicative network $f^{\text{MA}} : [-M, M]^3 \to \mathbb{R}$ (MA stands for 'Multiplicative Analytic') of depth $L_\epsilon = \mathcal{O}(\frac{1}{\log_2 s} \log_2 \frac{C_K}{\epsilon})$ with $G_\epsilon = \mathcal{O}(\frac{1}{\log_2 s} \log_2 \frac{C_K}{\epsilon})$ neurons that satisfies $\|f^{\text{MA}}(x, x, x) - K(x)\|_{L^\infty([-M,M])} \leq \epsilon$.*

Theorem 2 establishes that deep multiplicative networks with second-degree multiplications can approximate any real-valued analytic function that is bounded on the Bernstein s-ellipse E_s^M with error bounded by a quantity that decreases exponentially with the depth of the network.

In (Montanelli et al., 2021), the authors show that the kernel may be approximated with depth $L_\epsilon = \mathcal{O}(\frac{1}{\log_2^2 s} \log_2^2 \frac{C_K}{\epsilon})$ with $G_\epsilon = \mathcal{O}(\frac{1}{\log_2^2 s} \log_2^2 \frac{C_K}{\epsilon})$ neurons. In contrast, our approach achieves a $\mathcal{O}(\log(1/\epsilon))$ improvement in depth and a $\mathcal{O}(\log(1/\epsilon))$ in the number of neurons.

Approximation of bandlimited functions. As a next step, we study the ability of neural networks to approximate bandlimited functions. We start by showing how bandlimited functions can be approximated using analytic kernels. For this purpose, we will use Maurey's theorem (Pisier, 1980-1981; Vitali D. Milman, 1986) that states that for Hilbert subspaces with a bounded norm, any function in the convex hull can be easily approximated using points from the subspace, where the rate of approximation depends on the number of points used.

The following theorem shows that a deep multiplicative network can approximate in $B = [0, 1]^d$, a bandlimited function up to a given error tolerance using a relatively small number of neurons and depth.

Theorem 3. *Let $\epsilon \in (0, 1)$, $M > 1, d \geq 2$, and $K : \mathbb{R} \to \mathbb{C}$ be an analytic kernel that holds the assumptions of Theorem 2 with respect to $s > 2, C_K > 0$, and bounded by a constant $D_K \in (0, 1]$ on $[-dM, dM]$. Let f be a real-valued function in $\mathcal{H}_{K,M}(B)$. Further, let $F : [-M, M]^d \to \mathbb{C}$ be a square-integrable function such that $f(x) = \int_{[-M,M]^d} F(\omega) K(\omega \cdot x) \, d\omega$. We define $C_F = \int_{\mathbb{R}^d} |F(\omega)| \, d\omega = \int_{[-M,M]^d} |F(\omega)| \, d\omega$. Then, there exists a deep multiplicative network $f^{\text{MBL}} : B \to \mathbb{R}$ (MBL stands for 'Multiplicative bandlimited') of depth $L_\epsilon = \mathcal{O}\left(\frac{1}{\log_2 s} \log_2 \frac{C_F C_K}{\epsilon}\right)$ with $G_\epsilon = \mathcal{O}\left(\frac{C_F^2}{\epsilon^2 \log_2 s} \log_2 \frac{C_F C_K}{\epsilon}\right)$ neurons that satisfies $\|f^{\text{MBL}} - f\|_{L^2(B)} \leq \epsilon$.*

According to the above theorem, one can approximate bandlimited functions up to error ϵ using multiplicative neural networks of depth $L_\epsilon = \mathcal{O}(\log(1/\epsilon))$ using $G_\epsilon = \mathcal{O}(\epsilon^{-2} \log(1/\epsilon))$ neurons. In comparison, Montanelli et al. (2021) showed that one can approximate bandlimited functions to the same level of approximation using ReLU networks of depths $L_\epsilon = \mathcal{O}(\log^2(1/\epsilon))$ with $G_\epsilon = \mathcal{O}(\epsilon^{-2} \log^2(1/\epsilon))$ neurons. This result demonstrates the parameter efficiency of multiplicative networks in comparison with standard ReLU networks.

Approximation of Smooth Functions. We now turn to show results for Sobolev-Type functions. We use the results on bandlimited functions shown in Theorem 3 to approximate functions in $\mathcal{B}_{2r,2} \subsetneq \mathcal{W}^{r,2}$. We show that using slightly stronger assumptions, we get an approximation rate comparable to those shown by Barron (1993) (where the network is a shallow sigmoidal network model) using multiplicative networks (i.e. without non-linear activations). Further, since these are in fact in $\mathcal{W}^{r,2}$, we may better characterize such functions.

Theorem 4. *Let $d \geq 2, r \in \mathbb{N}$, $f \in \mathcal{B}_{2r,2}$ and $\epsilon > 0$. There exists a deep ReLU network f^{RS} (standing for "ReLU Sobolev") with a depth of $L_\epsilon = \mathcal{O}(d^2 \epsilon^{-2/r})$ and $G_\epsilon = \mathcal{O}(d^2 \epsilon^{-(2+2/r)})$ neurons, such that $\|f^{\text{RS}} - f\|_{L_2(B)} \leq \epsilon$.*

Theorem 5. *Let $d \geq 2, r \in \mathbb{N}$, $f \in \mathcal{B}_{2r,2}$ and $\epsilon > 0$. There exists a deep ReLU network f^{MS} (standing for "Multiplicative Sobolev") with a depth of $L_\epsilon = \mathcal{O}(d\epsilon^{-1/r})$ and $G_\epsilon = \mathcal{O}(d\epsilon^{-(2+(1/r))})$ neurons, such that $\|f^{\text{MS}} - f\|_{L_2(B)} \leq \epsilon$.*

In the following corollary, we demonstrate an application of Theorem 5 for approximating functions belonging to the Sobolev space $\mathcal{W}^{r,2}$ with an integrable Fourier transform.

Corollary 1. *Let $d \geq 2, r \in \mathbb{N}$, $f \in \mathcal{W}^{r,2}$ such that $\|\mathcal{F}f\|_{L_1(\mathbb{R}^d)} < \infty$, and $\epsilon > 0$. There exists a deep ReLU network f^{MS} (standing for "Multiplicative Sobolev") with a depth of $L_\epsilon = \mathcal{O}(\epsilon^{-1/r})$ and $G_\epsilon = \mathcal{O}(\epsilon^{-(2+(1/r))})$ neurons, such that $\|f^{\text{MS}} - f\|_{L_2(B)} \leq C \max\{|f|_{r,2}^2, \|\mathcal{F}f\|_1\}\epsilon$, where $C > 0$ is a constant dependent on r, d.*

Proof of Theorem 5. Let $f \in \mathcal{B}_{2r,2}$. We would like to approximate f using a bandlimited function f_M and then approximate f_M using a multiplicative neural network f^{MS} (standing for "Multiplicative Sobolev"). Let $M > 1$ be a band.

We recall the Inverse Fourier transform given by $(\mathcal{F}^{-1}g)(x) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} g(\omega) \exp(i\omega \cdot x) \, d\omega$. We define the bandlimiting of $f : \mathbb{R}^d \to \mathbb{R}$ as $f_M = \mathcal{F}^{-1}(\mathcal{F}f \mathbb{1}_{[-M,M]^d})$, such that $f_M \in \mathcal{H}_{K,M}(B)$ for $K(x) = \exp(ix)$ and $F = \frac{1}{(2\pi)^d} \mathcal{F}f$. This amounts to only taking frequencies in the band $[-M, M]^d$ in the Fourier representation of f. We have

$$\|f - f_M\|_{L_2(B)} \leq \left(\frac{1}{(2\pi)^d} \left\|\mathcal{F}f - \mathcal{F}f \mathbb{1}_{[-M,M]^d}\right\|_{L_2(\mathbb{R}^d)}^2\right)^{1/2} = \left(\frac{1}{(2\pi)^d} \int_{\mathbb{R}^d \setminus [-M,M]^d} |\mathcal{F}f(\omega)|^2 \, d\omega\right)^{1/2}.$$

For any $\omega \in \mathbb{R}^d \setminus [-M, M]^d$, we have $|M^{-1}\omega|^{2r} \geq 1$. Therefore,

$$
\begin{aligned}
\left(\frac{1}{(2\pi)^d} \int_{\mathbb{R}^d \setminus [-M,M]^d} |\mathcal{F}f(\omega)|^2 \, d\omega \right)^{1/2} &\leq \left(\frac{1}{(2\pi)^d} \int_{\mathbb{R}^d \setminus [-M,M]^d} \left| M^{-1}\omega \right|^{2r} |\mathcal{F}f(\omega)|^2 \, d\omega \right)^{1/2} \\
&\leq M^{-r} \left(\frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |\omega|^{2r} |\mathcal{F}f(\omega)|^2 \, d\omega \right)^{1/2} \\
&\leq M^{-r},
\end{aligned}
$$

where the final inequality follows from the fact that $f \in \mathcal{B}_{2r,2}$. For any $\epsilon > 0$, we set $M = (2/\epsilon)^{1/r}$. We will construct a neural network f^{MS} to approximate the bandlimited function f_M, such that $\|f_M - f^{\mathrm{MS}}\|_{L_2(B)} \leq \epsilon/2$. Assuming we have constructed such f^{MS}, then by the triangle inequality we then arrive at

$$
\|f - f^{\mathrm{MS}}\|_{L_2(B)} \leq \|f - f_M\|_{L_2(B)} + \|f_M - f^{\mathrm{MS}}\|_{L_2(B)} \leq M^{-r} + \epsilon/2 \leq \epsilon.
$$

Let us define the function $F : [-M, M]^d \to \mathbb{C}$ as follows $F(\omega) = \frac{1}{(2\pi)^d}(\mathcal{F}f)(\omega)$. We then have the following identity

$$
f_M(x) = \int_{[-M,M]^d} F(\omega) K(\omega \cdot x) \, d\omega = \int_{[-M,M]^d} \frac{1}{(2\pi)^d} \mathcal{F}f(\omega) \exp(i\omega \cdot x) \, d\omega.
$$

We may now work under the conditions of Theorem 3. We consider that $C_F = \int_{[-M,M]^d} |F(\omega)| \, d\omega = \frac{1}{(2\pi)^d} \int_{[-M,M]^d} |\mathcal{F}f(\omega)| \, d\omega \leq 1$, where the inequality is due to the definition of $\mathcal{B}_{2r,2}$. The kernel $K(t) = \exp(it)$ takes as input $t = \omega \cdot x$, for $x \in B$ and $\omega \in [-M, M]^d$. Therefore, $t \in [-dM, dM]$, and $K : [-dM, dM] \to \mathbb{R}$. Since K is an entire function, it is continuable to E_s^{dM} for any $s > 2$, let us choose $s = 4$. We notice that $a_4^{dM} = dM(4 + 4^{-1})/2$ is the larger axis, and therefore the maximal norm of K on E_s^{dM} is given by $K(a_4^{dM})$:

$$
C_K = \max_t |K(t)| \leq \exp\left(dM \frac{4 + 4^{-1}}{2}\right).
$$

Further, for any $t \in \mathbb{R}$ we have $|K(t)| \leq 1 = D_K$. We now approximate f_M with a multiplicative network. Using the results of Theorem 3, there exists a deep multiplicative neural network f^{MS} that approximates the bandlimited function f_M in $L_2(B)$ with error bounded by $\epsilon/2$ and depth

$$
\begin{aligned}
L_\epsilon &\leq C_1 \frac{1}{\log_2 4} \log_2 \left(\frac{2 C_K C_F}{\epsilon} \right) \\
&\leq C_2 \frac{1}{\log_2 4} \log_2 \left(\frac{\exp(dM \frac{4 + 4^{-1}}{2})}{\epsilon} \right) \\
&= \frac{C_2}{2} \left(dM \frac{4 + 4^{-1}}{2 \log(2)} + \log_2(1/\epsilon) \right) \\
&\leq \frac{C_2}{2} (4dM + \log_2(1/\epsilon)) \\
&\leq C_2 \left(4d\epsilon^{-1/r} + \log_2(1/\epsilon) \right) \\
&\leq C_3 \cdot d\epsilon^{-1/r},
\end{aligned} \tag{2}
$$

for some constants $C_1, C_2, C_3 > 0$. The third step follows from $\log_2(xy) = \log_2(x) + \log_2(y)$ and $\log_a(\exp(x)) = x/\log(a)$ (for all $x, y, a > 0$) and the fifth inequality follows from substituting $M = (2/\epsilon)^{1/r}$. In addition, the number of neurons can be bounded by

$$
\begin{aligned}
G_\epsilon &\leq C_1' C_F^2 \cdot \epsilon^{-2} \log_2 \frac{2 C_K C_F}{\epsilon} \\
&\leq C_2' \cdot \epsilon^{-2} \log_2 \frac{\exp(dM \frac{4 + 4^{-1}}{2})}{\epsilon} \\
&\leq C_2' \cdot \epsilon^{-2} (3d(2/\epsilon)^{1/r} + \log_2(1/\epsilon)) \\
&\leq C_3' \cdot d\epsilon^{-(2 + 1/r)},
\end{aligned} \tag{3}
$$

for some constants $C_1', C_2', C_3' > 0$. $\qquad \square$

Theorems 4-5 provide insights into several interesting properties of the Sobolev-Type ball $\mathcal{B}_{2r,2}$. First, we see that approximating these functions does not suffer from the curse of dimensionality that occurs when approximating the full Sobolev space. Secondly, for both ReLU networks and multiplicative networks, the bound decreases as the smoothness r increases, which is a desirable property for approximation error bounds. In fact, as r approaches infinity, the bound approaches the one proposed in (Barron, 1993). Lastly, we show that for the same error tolerance ϵ, multiplicative neural networks can approximate a target function $f \in \mathcal{B}_{2r,2}$ with a depth of $\mathcal{O}(d\epsilon^{-1/r})$ and $\mathcal{O}(d\epsilon^{-(2+1/r)})$ neurons, while standard ReLU neural networks require a depth of $\mathcal{O}(d^2\epsilon^{-2/r})$ and $\mathcal{O}(d^2\epsilon^{-(2+2/r)})$ neurons. This result demonstrates that multiplicative neural networks have stronger approximation guarantees when approximating functions in the Sobolev-Type space.

4 Experiments

In previous sections, we demonstrated that multiplicative networks have lower complexity requirements for approximating certain target functions when compared to multilayer perceptrons. To validate these results empirically, we analyzed the influence of network complexity such as depth and width on the network's approximation error. To do so, we approximated Chebyshev polynomials of varying degrees T_n using multilayer perceptrons and multiplicative networks with increasing complexities (i.e., depth, width). As the degree of the Chebyshev polynomials increased, we expected multilayer perceptrons to struggle in approximating high-degree polynomials. Conversely, as proven in Lemma 1, T_n can be perfectly constructed using a multiplicative network with depth $L_n = n$ and width $G_n = 3n$.

To validate Theorems 4 and 5, we approximated randomly generated Gaussian mixtures. Specifically, we consider functions of the following form

$$f(x; \mu, \Sigma) := \frac{1}{N} \sum_{i=1}^{N} \frac{1}{(2\pi)^{d/2}|\Sigma_i|^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_i)^\top \Sigma_i^{-1}(x - \mu_i)\right),$$

where $\Sigma \in \mathbb{R}^{N \times d \times d}$ and $\mu \in \mathbb{R}^{N \times d}$. We sample μ_i uniformly from $[0,1]^d$ and Σ_i uniformly from $[0, 0.4]^d$. It is straightforward to show that Gaussian mixtures are in the Schwartz class (Schwartz, 1950). This implies that they are in $\mathcal{W}^{r,2}$, and that $\mathcal{F}f \in L_1(\mathbb{R}^d)$, which in turn means that they are also members of $\mathcal{B}_{2r,2}$ up to a constant factor (similar to the target functions considered in Corollary 1).

Estimating the approximation error of a model for a given target function is generally a challenging problem. In the literature, this is usually done by training the model to fit the target function. However, the approximation error may differ from the estimation due to optimization issues, such as sub-optimal initialization and improperly tuned hyperparameters. To obtain a more precise estimation of the approximation error, we trained each model using 10 different initialization seeds and selected the minimal test mean squared error (MSE) loss of the model. This approach helped us avoid problems related to poor initialization.

In Figure 1, we approximated T_{12} and T_{15} using networks whose depth and width varied simultaneously. The models were trained using the Adam optimizer with a learning rate of 0.001 for 100 epochs and a batch size of 64 to minimize their Mean Squared Error (MSE) (with respect to the target function). We used 1000 training and 1000 test samples that were uniformly selected at random from $[0,1]$. As shown, multiplicative networks achieved better results (lower errors) compared to multilayer perceptrons with the same depth and width.

In Figure 2, we approximated T_n of degrees $n = 9, 11, 13$ using multilayer perceptrons and multiplicative networks with depth n and width 10. We used the same training and testing processes as in the previous experiment. As can be seen, multiplicative networks converged to a zero loss faster and provided better approximation rates for the given polynomials. For the code for generating the experiments, see Appendix B.

We conducted experiments to approximate the mixtures of Gaussians using multilayer perceptrons and multiplicative networks, while varying the dimensions and number of Gaussians (d and N, respectively). All networks had a depth of 5 and a width of 10. We plotted the averaged approximation errors during training over 20 initialization seeds, along with their corresponding 95% confidence intervals, while fixing the target function. The training was performed with the same hyperparameters as in the previous experiments, except for the learning rate, which was set to 10^{-4}.
T_{12} T_{15}

Figure 1: **Approximating Chebychev polynomials with networks of increasing complexity.** We present the minimal test mean squared error (MSE) loss for approximating Chebychev polynomials T_n using networks with increasing complexity, utilizing 10 initialization seeds. The network complexity (x-axis) is defined as (depth, width) and is increased linearly.

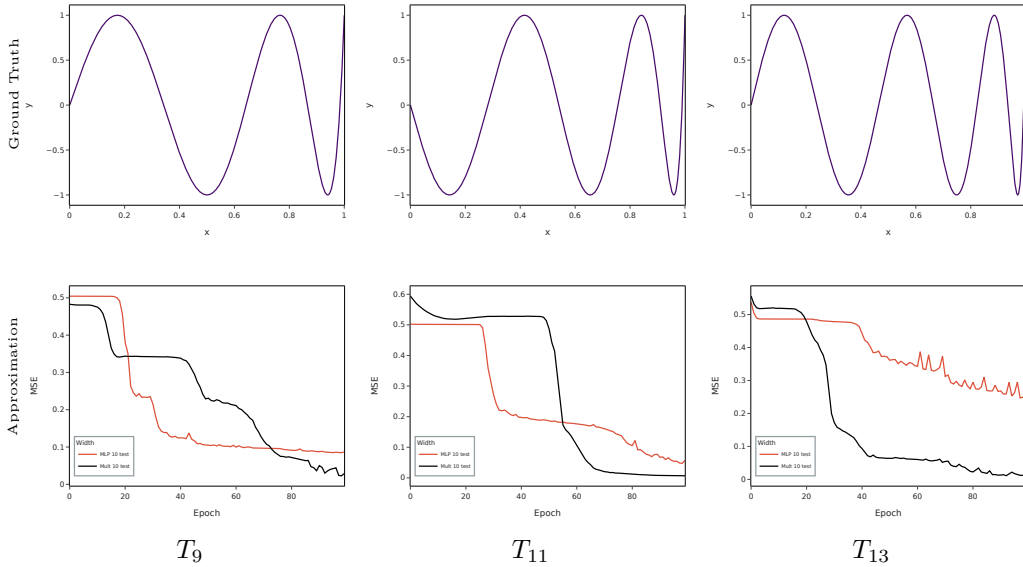

T_9 T_{11} T_{13}

Figure 2: **Approximating Chebychev polynomials.** We present the minimal test mean squared error (MSE) loss for approximating Chebychev polynomials T_n, using networks of depth n and width 10, with 10 initialization seeds. The first row displays the actual polynomials, and the second row shows the approximation errors using both multilayer perceptrons and multiplicative networks.

Our results, shown in Figure 3, indicate that multiplicative networks outperform multilayer perceptrons in terms of approximation errors across various dimensions and numbers of Gaussians. Interestingly, we also observed that training with multiplicative networks converges much faster than with multilayer perceptrons.

5 Conclusions

Previous papers have studied the approximation guarantees of standard fully-connected neural networks to approximate functions in the Barron space $\mathcal{B}_{1,1}$ (Barron, 1993), the space of bandlimited functions (Montanelli
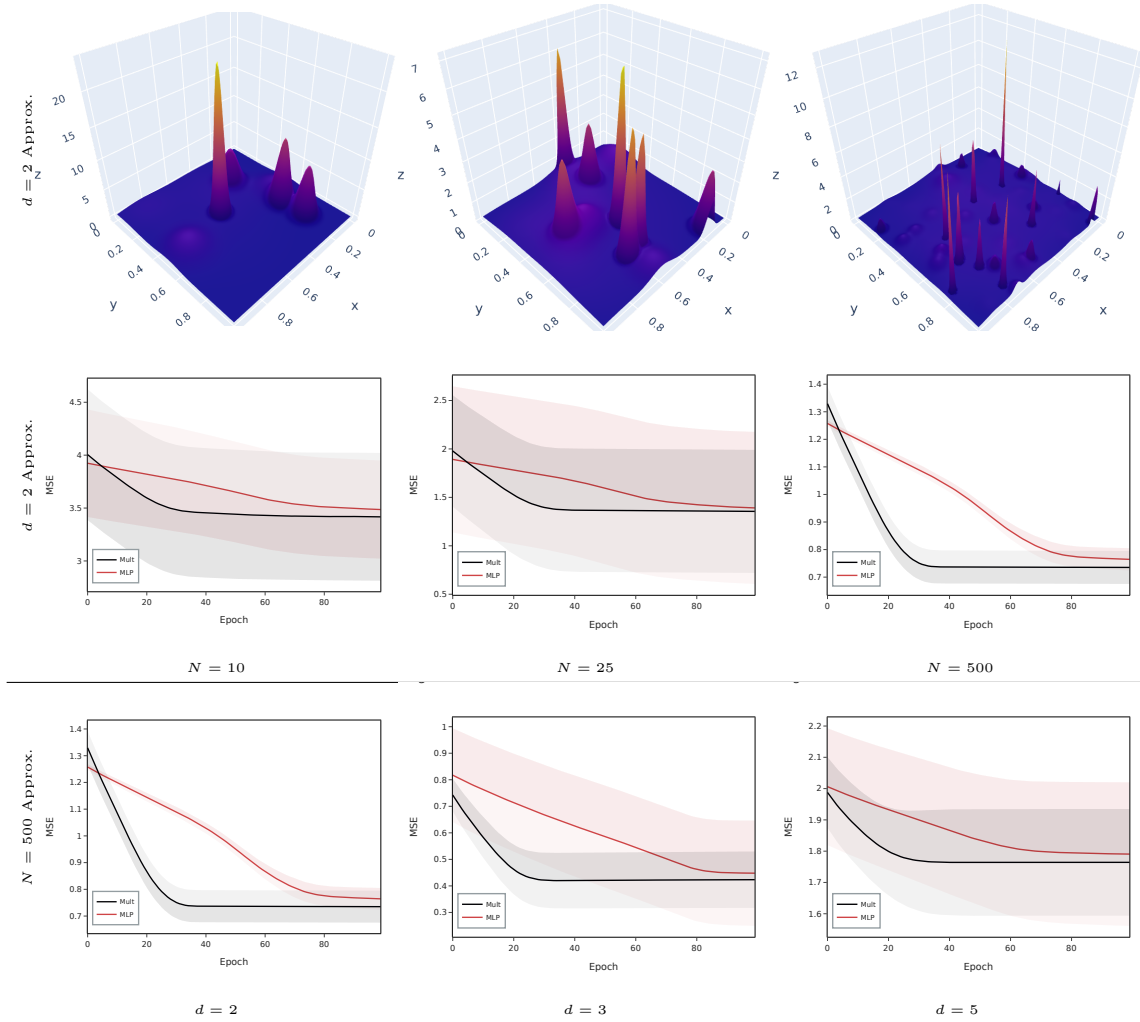

Figure 3: **Approximating Gaussian mixtures with a varying number of Gaussians and dimensions.** We plot the test mean squared error (MSE) loss obtained by approximating Gaussian mixtures $f(x; \mu, \Sigma)$ where $\mu \in \mathbb{R}^{N \times d}$ and $\Sigma \in \mathbb{R}^{N \times d \times d}$ using multiplicative and ReLU networks for different values of d and N. We report their errors averaged over 20 initialization seeds along with their corresponding 95% confidence intervals.

et al., 2021), and the Korobov space (Blanchard & Bennouna, 2022a). These studies have shown that fully-connected networks can approximate a wide range of smooth functions without suffering from the curse of dimensionality and have provided insights into the tradeoffs between the width and depth of neural networks in learning certain types of functions. However, these results are limited to variants of fully-connected network and do not provide information about other types of architectures.

In this paper, we extend these results by exploring the approximation guarantees of both multiplicative neural networks and standard fully-connected networks to approximate bandlimited functions and members of the Sobolev-Type ball $\mathcal{B}_{2r,2}$. Our results show that multiplicative neural networks achieve stronger approximation guarantees compared to standard ReLU networks. In addition, we show that, unlike the Barron space and the space of bandlimited functions, $\mathcal{B}_{2r,2}$ is a subset of the Sobolev space $\mathcal{W}^{r,2}$. Therefore, our results demonstrate that it is possible to avoid the curse of dimensionality for wide subsets of the Sobolev space.

A Examples

Example 1. *Let $f \in L_2(\mathbb{R}^d)$ such that f is Bandlimited function with band π (i.e., $\mathrm{supp}(\mathcal{F}f) \subset [-\pi, \pi]^d$). Let $\phi(x) = \mathrm{sinc}(x) = \sin(\pi x)/\pi x$, and $\phi_k = \phi(\cdot - k)$ for all $k \in \mathbb{Z}^d$. By the Shannon-Nyquist theorem (Shannon, 1984), we have:*

$$f(x) = \sum_{k \in \mathbb{Z}^d} \langle f, \phi_k \rangle \phi_k(x) = \sum_{k \in \mathbb{Z}^d} f(k)\phi(x - k).$$

This means that every Bandlimited function can be completely determined using a discrete set of integer samples. This result is particularly surprising for high-dimensional functions (d is large) since the maximal distance between a point x and a sampling point grows with d. For example, the vertex of the unit cube in $\mathbb{R}^d$ is of distance $\sqrt{d}/2$ away from its center. Despite this, we can still recover samples from the integer vertices, even when the distances scale as $\sqrt{d}$. This property is useful when recovering high-dimensional functions using neural networks. See Figure 4 for illustration.

Figure 4: Illustration of Example 1. A bandlimited function f can be reconstructed using a discrete set of values, despite the fact that the distances in each cube grow as $\mathcal{O}(\sqrt{d})$.

B Code

In this section, we provide the code used to generate the experiments. The network architectures are described in Section 2.2. The "chebychev(n, x)" function calculates the Chebyshev polynomial of degree n for a given input x. The "MLPPolynomialApproximation" and "MultPolynomialApproximation" classes are Pytorch Lightning (Falcon et al., 2019) implementations for the multilayer perceptrons and multiplicative networks, respectively. The "MultiplicativeLayer" class is based on the standard linear layer in PyTorch (Paszke et al., 2019). Since the neurons in each layer are interchangeable, we arbitrarily connected the first two neurons in each layer using a multiplicative operation. In each network, the layers are followed by ReLU activations.

```

$$D = 5 \qquad\qquad D = 20 \qquad\qquad D = 30$$

Figure 5: **Approximating Gaussian mixtures with a varying number of Gaussians and dimensions.** We plot the test mean squared error (MSE) loss obtained by approximating Gaussian mixtures $f(x; \mu, \Sigma)$ where $\mu \in \mathbb{R}^{N \times d}$ and $\Sigma \in \mathbb{R}^{N \times d \times d}$ using multiplicative and ReLU networks for different values of d and N. We report their errors averaged over 20 initialization seeds along with their corresponding 95% confidence intervals.

```python
def train_dataloader(self):
    return torch.utils.data.DataLoader(self.train_dataset, batch_size=64, shuffle=True
        )

def val_dataloader(self):
    return torch.utils.data.DataLoader(self.val_dataset, batch_size=32, shuffle=False)

def configure_optimizers(self):
    optimizer = optim.Adam(self.parameters(), lr=1e-3)
    return optimizer
```

C Additional Experiments

In this section, we add plots regarding approximation in higher dimensions d, shown in Figure 5. We conducted the exact same experiment as in the bottom row of Figure 3 with $N = 500$ and $d = 5, 20, 30$. As can be seen, both architectures are able to achieve near 0 error, yet we still see faster convergence using multiplicative networks over multilayer perceptrons.

D Proofs

Definition 4. *For two Banach spaces V_1 and V_2, we say that V_1 is embedded in V_2 if $\|u\|_{V_2} \leq C\|u\|_{V_1}$ for some constant C and for $u \in V_1$.*

Lemma 2. *Let $r > 0$ and $d \geq 2$. Then, $\mathcal{B}_{2r,2}$ is embedded as a proper subspace of $\mathcal{W}^{r,2}$.*

Proof. Since $f \in \mathcal{B}_{2r,2}$, we have $f \in L_2(\mathbb{R}^d)$, and therefore, $\|f\|_2 < \infty$. Additionally, by Robert A. Adams (2003)(Theorem 5.2), there exists a constant $C_1 > 0$ such that

$$\|f\|_{\mathcal{W}^{r,2}} \leq C_1(\|f\|_2 + |f|_{r,2}),$$

where C_1 is dependant on r and the dimension d. Therefore, it remains to prove that $|f|_{r,2}$ is bounded. For this, we use some properties of multivariate function spaces.

We begin with the following claim that we will use in advance. Let $\omega \in \mathbb{R}^d, d \geq 2$, we have

$$|\omega|^{2r} = \|\omega\|_{l_2}^{2r} = \left(\sum_{m=1}^{d} \omega_m^2\right)^r = \sum_{\|\alpha\|_1 = r} \binom{r}{\alpha_1, \ldots, \alpha_d} \cdot (\omega^\alpha)^2, \tag{4}$$

where $\omega^\alpha = \prod_{i=1}^{d} \omega_i^{\alpha_i}$ for $\alpha \in \mathbb{R}^d$.

By Jensen's inequality,

$$|f|_{r,2}^2 = \left(\sum_{\alpha : |\alpha| = r} \|D^\alpha f\|_2\right)^2 \leq d^r \sum_{\alpha : |\alpha| = r} \|D^\alpha f\|_2^2$$

By Parseval's Identity in $\mathbb{R}^d$ (Albrecht et al., 2021):

$$\|D^\alpha f\|_2^2 = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |\mathcal{F}(D^\alpha f)(\omega)|^2 \, d\omega = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |(\mathcal{F}f)(\omega)|^2 |\omega^\alpha|^2 \, d\omega.$$

Hence, by (4)

$$\sum_{\alpha : |\alpha| = r} \|D^\alpha f\|_2^2 = \sum_{\alpha : |\alpha| = r} \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |(\mathcal{F}f)(\omega)|^2 |\omega^\alpha|^2 \, d\omega$$

$$\leq \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |(\mathcal{F}f)(\omega)|^2 \left(\sum_{\alpha : |\alpha| = r} \binom{r}{\alpha_1, \ldots, \alpha_d} \cdot |\omega^\alpha|^2\right) \, d\omega$$

$$= \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |\mathcal{F}f(\omega)|^2 |\omega|^{2r} \, d\omega.$$

where the inequality follows from the fact that $\binom{r}{\alpha_1, \ldots, \alpha_d} \geq 1$. Finally, we conclude that

$$\|f\|_{\mathcal{W}^{r,2}} \leq C_1(\|f\|_2 + |f|_{r,2}) \leq C_1\left(\|f\|_2 + \frac{d^r}{(2\pi)^{d/2}} \left(\int_{\mathbb{R}^d} |(\mathcal{F}f)(\omega)|^2 |\omega|^{2r} \, d\omega\right)^{1/2}\right)$$

$$\leq C_2 \|f\|_{\mathcal{B}_{2r,2}},$$

for some $C_1, C_2 > 0$, where the second inequality is due to the definition of $\|\cdot\|_{\mathcal{B}_{2r,2}}$ as given in equation 1.

To see that $\mathcal{B}_{2r,2}$ is a proper subspace of $\mathcal{W}^{r,2}$, we present an example function $f \in \mathcal{W}^{r,2}(\mathbb{R}^d)$, such that $f \notin \mathcal{B}_{2r,r}$. Let $\epsilon > 0$ and d, r such that $2r + \epsilon < d$. We define the function $f \in \mathcal{W}^{r,2}(\mathbb{R}^d)$ through its Fourier transform:

$$\mathcal{F}f(\omega) = \begin{cases} 1 & |\omega| \leq 1 \\ |\omega|^{-(r+(d+\epsilon)/2)} & |\omega| > 1. \end{cases}$$

Indeed, $f \in \mathcal{W}^{r,2}(\mathbb{R}^d)$ since:

$$\int_{\mathbb{R}^d} |\omega|^{2r} |\mathcal{F}f(\omega)|^2 \, d\omega = \int_{|\omega| \leq 1} |\omega|^{2r} |\mathcal{F}f(\omega)|^2 d\omega + \int_{|\omega| > 1} |\omega|^{2r} |\mathcal{F}f(\omega)|^2 \, d\omega$$

$$\leq 1 + \int_{|\omega| > 1} |\omega|^{-(d+\epsilon)} \, d\omega < \infty.$$

We have shown above that $|f|_{r,2}^2 \leq d^r \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |\mathcal{F}f(\omega)|^2 |\omega|^{2r} d\omega$, and so $f \in \mathcal{W}^{r,2}(\mathbb{R}^d)$. Let us see that $\mathcal{F}f(\omega) \notin L_1$. Since $2r + \epsilon < d \Rightarrow r + (d+\epsilon)/2 < d$, the following integral diverges

$$\int_{\mathbb{R}^d} |\mathcal{F}f(\omega)| d\omega = \int_{|\omega| < 1} |\mathcal{F}f(\omega)| d\omega + \int_{|\omega| > 1} |\mathcal{F}f(\omega)| d\omega$$

$$= \int_{|\omega| < 1} |\mathcal{F}f(\omega)| d\omega + \int_{|\omega| > 1} |\omega|^{-(r+(d+\epsilon)/2)} d\omega.$$
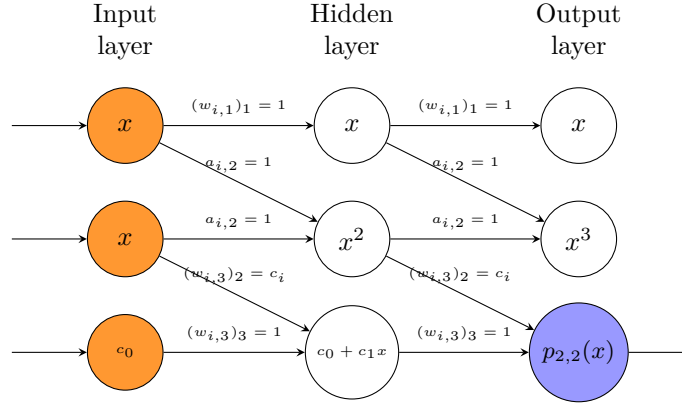

Figure 6: Illustration of the multiplicative network in Proof of Lemma 1, where the polynomial degree $n = 2$.

That is because the second term diverges if and only if $r + (d + \epsilon)/2 < d$ and the first term converges for all d, r, ϵ. This implies that f does not satisfy the condition $\frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |\mathcal{F}f(\omega)| d\omega \leq 1$ which is a necessary requirement for membership in $\mathcal{B}_{2r,2}$. $\qquad\square$

Lemma 1. *For any polynomial $p_n : \mathbb{R} \to \mathbb{R}$ of degree n of the form $p_n(x) = \sum_{k=0}^{n} c_k x^k$, there exists a multiplicative neural network $f_n^{\mathrm{POL}} : \mathbb{R}^3 \to \mathbb{R}$, of depth $L_n = \mathcal{O}(n)$ with $G_n = \mathcal{O}(n)$ neurons that satisfies $f_n^{\mathrm{POL}}(x, x, c_0) = p_n(x)$ for $c_0 \in \mathbb{R}$, and $x \in \mathbb{R}$.*

Proof. Let $p_n(x) = \sum_{k=0}^{n} c_k x^k$ be a polynomial of degree n and $p_{n,i} = \sum_{k=0}^{i} c_k x^k$ its partial sum up to term i. We construct a network f_n^{POL} whose ith layer satisfies:

$$(f_n^{\mathrm{POL}})_i(x, x, c_0) = (x, x^{i+1}, p_{n,i}(x)).$$

We notice that in this construction, the input of the network is a three-dimensional vector composed of the input x and the first coefficient c_0. We construct the network by specifying its weights as defined in Definition 2. At layer i, the model weights for the three neurons are defined as:

$$w_{i,1} = (1, 0, 0), \quad a_{i,2} = 1 \text{ for } (j_1, j_2) = (1, 2), \quad w_{i,3} = (0, c_i, 1)$$

The rest of the weights are zeros. In Figure 6, we plot the proposed architecture.

We argue that at any layer $i \geq 0$, neuron 1 contains x, neuron 2 contains x^{i+1} and neuron 3 contains $p_{n,i}(x)$. Let $y_{i+1,1}, y_{i+1,2}, y_{i+1,3}$ be the three neurons in layer $i + 1$. Let us address each claim individually. Since the only non-zero weight affecting the first neuron is in $w_{i+1,1}$, $y_{i+1,1} = y_{i,1} = x$ by the assumption. The only non-zero weight affecting the second neuron appears in $a_{i=1,2}$, the weight affecting the multiplicative interaction, and therefore $y_{i+1,2} = y_{i,1} y_{i,2} = x^{i+1}$. Lastly, $y_{i+1,3}$ depends only on $w_{i+1,3}$, and so $y_{i+1,3} = c_{i+1} y_{i,2} + y_{i,3} = p_{n,i}(x) + c_{i+1} x^{i+1} := p_{n,i+1}(x)$. We conclude using the fact that $p_{n,n}(x) = p_n(x)$. The third neuron in the final layer then holds the value $p_n(x)$. $\qquad\square$

Theorem 2. *Let $M \geq 1$, $s > 2$, $C_K > 0$ and $\epsilon \in (0, 1)$ be scalars. Then, for any real-valued analytic function $K : [-M, M] \to \mathbb{R}$ that is analytically continuable to the ellipse E_s^M where $|K(x)| \leq C_K$, there exists a deep multiplicative network $f^{\mathrm{MA}} : [-M, M]^3 \to \mathbb{R}$ (MA stands for 'Multiplicative Analytic') of depth $L_\epsilon = \mathcal{O}(\frac{1}{\log_2 s} \log_2 \frac{C_K}{\epsilon})$ with $G_\epsilon = \mathcal{O}(\frac{1}{\log_2 s} \log_2 \frac{C_K}{\epsilon})$ neurons that satisfies $\|f^{\mathrm{MA}}(x, x, x) - K(x)\|_{L^\infty([-M,M])} \leq \epsilon$.*

Proof. Let $M \geq 1$, $s > 2$, $C_K > 0$, $\epsilon \in (0, 1)$ and let K be a real-valued analytic function with the required assumptions with respect to s, C_K. We wish to construct a network that approximates K. As a first step, we approximate K with a polynomial h_n of degree $n \geq 2$ (to be defined later). Then, we realize h_n with a deep

multiplicative network as proposed in Lemma 1. Since K maintains the specifications in Theorem 1, there exists a polynomial h_n, such that for any integer $n \geq 2$, we have

$$\|h_n - K\|_{L^\infty([-M,M])} \leq \frac{C_K s^{-n}}{s-1} = \mathcal{O}(C_K s^{-n}).$$

By choosing $n = \frac{1}{\log_2 s} \log_2 \frac{C_K}{\epsilon(s-1)} \leq \frac{1}{\log_2 s} \log_2 \frac{C_K}{\epsilon}$ (since $s > 2$), we obtain the following relation:

$$
\begin{aligned}
\frac{\epsilon(s-1)}{C_K} &= 2^{\log_2(\frac{\epsilon(s-1)}{C_K})} \\
&= 2^{-\frac{1}{\log_2 s}(\log_2(\frac{C_K}{\epsilon(s-1)}))\log_2 s} \\
&= s^{-\frac{1}{\log_2 s}(\log_2(\frac{C_K}{\epsilon(s-1)}))} = s^{-n}.
\end{aligned}
\tag{5}
$$

In particular,

$$\|h_n - K\|_{L^\infty([-M,M])} \leq \frac{C_K s^{-n}}{s-1} \leq \epsilon,$$

for $s \geq 1$. Given that h_n is a polynomial of degree n, by Lemma 1, there exists f^{POL} and $c_0 = h_{n,0}$ such that $h_n(x) = f^{\mathrm{POL}}(x, x, c_0)$, and achieve the required bound. $\qquad \square$

Let us now recall Maurey's Theorem (Pisier, 1980-1981; Vitali D. Milman, 1986) which will assist us in the proof of Theorem 3.

Lemma 3 (Maurey's theorem). *Let $\mathcal{V}$ be a Hilbert space with norm $\|\cdot\|_{\mathcal{V}}$. Suppose there exists $Q \subset \mathcal{V}$ such that for every $q \in Q$, $\|q\|_{\mathcal{V}} \leq b$ for some $b > 0$. Then, for every f in the convex hull of Q and every integer $n \geq 1$, there exists a f_n in the convex hull of n points in Q and a constant $c > b^2 - \|f\|_{\mathcal{V}}^2$ such that $\|f_n - f\|_{\mathcal{V}}^2 \leq \frac{c}{n}$.*

Theorem 3. *Let $\epsilon \in (0,1)$, $M > 1, d \geq 2$, and $K : \mathbb{R} \to \mathbb{C}$ be an analytic kernel that holds the assumptions of Theorem 2 with respect to $s > 2, C_K > 0$, and bounded by a constant $D_K \in (0,1]$ on $[-dM, dM]$. Let f be a real-valued function in $\mathcal{H}_{K,M}(B)$. Further, let $F : [-M, M]^d \to \mathbb{C}$ be a square-integrable function such that $f(x) = \int_{[-M,M]^d} F(\omega)K(\omega \cdot x) \, d\omega$. We define $C_F = \int_{\mathbb{R}^d} |F(\omega)| \, d\omega = \int_{[-M,M]^d} |F(\omega)| \, d\omega$. Then, there exists a deep multiplicative network $f^{\mathrm{MBL}} : B \to \mathbb{R}$ (MBL stands for 'Multiplicative bandlimited') of depth $L_\epsilon = \mathcal{O}\left(\frac{1}{\log_2 s} \log_2 \frac{C_F C_K}{\epsilon}\right)$ with $G_\epsilon = \mathcal{O}\left(\frac{C_F^2}{\epsilon^2 \log_2 s} \log_2 \frac{C_F C_K}{\epsilon}\right)$ neurons that satisfies $\|f^{\mathrm{MBL}} - f\|_{L^2(B)} \leq \epsilon$.*

Proof. Let $f \in \mathcal{H}_{K,M}(B)$. Further, let $F(\omega) = |F(\omega)| \cdot \exp(i\theta(\omega))$, the polar representation of $F(\omega)$. We may write f through its Fourier representation:

$$
\begin{aligned}
f(x) &= \mathrm{Re}\left(\int_{[-M,M]^d} F(\omega)K(\omega \cdot x) \, d\omega\right) \\
&= \mathrm{Re}\left(\int_{[-M,M]^d} C_F \exp(i\theta(\omega))K(\omega \cdot x)\frac{|F(\omega)|}{C_F} \, d\omega\right) \\
&= \int_{[-M,M]^d} C_F[\cos(\theta(\omega))K_R(\omega \cdot x) - \sin(\theta(\omega))K_I(\omega \cdot x)]\frac{|F(\omega)|}{C_F} \, d\omega,
\end{aligned}
\tag{6}
$$

where K_R, K_I are the real and imaginary parts of K respectively. Equation 6 represents f as an infinite convex combination of functions in

$$Q_{K,M} = \left\{\gamma[\cos(\beta)K_R(\omega \cdot x) - \sin(\beta)K_I(\omega \cdot x)] \,\Big|\, |\gamma| \leq C_F, \beta \in \mathbb{R}, \omega \in [-M, M]^d\right\}.$$

This means that f is in the closure of the convex hull of $Q_{K,M}$. Due to the fact that $x \in [0,1]^d$ and $\omega \in [-M, M]^d$, $t = \omega \cdot x \in [-dM, dM]$. By the definition of D_K, functions in $Q_{K,M}$ are bounded in the

$L^2(B)$-norm by $2C_F D_K \leq 2C_F$. Using Lemma 3, there exist real coefficients $\{b_j\}$ and $\{\beta_j\}$, and vectors $\omega_j \in [-M, M]^d$ for $1 \leq j \leq \lceil 1/\epsilon_0^2 \rceil$, such that:

$$f_{\epsilon_0}(x) = \sum_{j=1}^{\lceil 1/\epsilon_0^2 \rceil} b_j [\cos(\beta_j) K_R(\omega_j \cdot x) - \sin(\beta_j) K_I(\omega_j \cdot x)], \quad \sum_{j=1}^{\lceil 1/\epsilon_0^2 \rceil} |b_j| \leq C_F,$$

for $0 < \epsilon_0 < 1$ to be defined at a later time, such that

$$\|f_{\epsilon_0}(x) - f(x)\|_{L^2(B)} \leq 2C_F \epsilon_0.$$

We are now ready to approximate $f_{\epsilon_0}(x)$ using a deep multiplicative neural network f^{MBL} (MBL stands for 'Multiplicative bandlimited') on B. We notice that $K_R(x)$ and $K_I(x)$ are analytic kernels that hold the assumptions of Theorem 2, for C_K, s, M, ϵ_0. They can therefore be approximated to ϵ_0 error using networks $f^{\mathrm{RMA}}, f^{\mathrm{IMA}}$ of depth and number of neurons

$$G_{\epsilon_0} \sim L_{\epsilon_0} = \mathcal{O}(\frac{1}{\log_2 s} \log_2 \frac{C_K}{\epsilon_0}),$$

where RMA stands for 'Real Multiplicative Analytic' and IMA stands for 'Imaginary Multiplicative Analytic'. Let us define the multiplicative network $f^{\mathrm{MBL}}(x)$ by

$$f^{\mathrm{MBL}}(x) = \sum_{j=1}^{\lceil 1/\epsilon_0^2 \rceil} b_j \big[\cos(\beta_j) f^{\mathrm{RMA}}(\omega_j \cdot x) - \sin(\beta_j) f^{\mathrm{IMA}}(\omega_j \cdot x) \big].$$

This network has depth $L_{\epsilon_0} = \mathcal{O}(\frac{1}{\log_2 s} \log_2 \frac{C_K}{\epsilon_0})$ and $G_{\epsilon_0} = \mathcal{O}(\frac{1}{\epsilon_0^2 \log_2 s} \log_2 \frac{C_K}{\epsilon_0})$ neurons.

$$
\begin{aligned}
\|f^{\mathrm{MBL}}(x) - f_{\epsilon_0}(x)\|_{L^\infty(B)} &\leq \sum_{j=1}^{\lceil 1/\epsilon_0^2 \rceil} |b_j| \|f^{\mathrm{RMA}}(\omega_j \cdot x) - K_R(\omega_j \cdot x)\|_{L^\infty(B)} \\
&+ \sum_{j=1}^{\lceil 1/\epsilon_0^2 \rceil} |b_j| \|f^{\mathrm{IMA}}(\omega_j \cdot x) - K_I(\omega_j \cdot x)\|_{L^\infty(B)} \\
&\leq 2C_F \epsilon_0,
\end{aligned}
$$

that implies

$$\|f^{\mathrm{MBL}}(x) - f(x)\|_{L^2(B)} \leq \|f^{\mathrm{MBL}}(x) - f_{\epsilon_0}(x)\|_{L^2(B)} + \|f_{\epsilon_0}(x) - f(x)\|_{L^2(B)} \leq 4C_F \epsilon_0,$$

where the last inequality is due to the fact that

$$\|g\|_{L^2(B)} = \left(\int_B |g|^2 \right)^{1/2} \leq \|g\|_{L^\infty(B)}.$$

Taking $\epsilon_0 = \epsilon/(4C_F)$ achieves the sought result. □

We further investigate how the constant C_K from Theorem 3 varies as a function of M and s. Let $K(x) = \exp(ix)$ be an example kernel, $x \in [-M, M]^d$. We notice that $a_s^M = M(s + s^{-1})/2$ for $s > 2$, is the larger axis, and therefore the maximal norm of K on E_s^M is given by $K(a_s^M)$:

$$\max_x |K(x)| \leq \exp(M \frac{s + s^{-1}}{2}) = C_K(s, M).$$

In our setting, inputs are in the interval $t = \omega \cdot x \in [-dM, dM]$, so we may use the bounding constant

$$\max_t |K(t)| \leq \exp(dM \frac{s + s^{-1}}{2}) = C_K(s, dM).$$

The resulting network f^{MBL} then has depth

$$L_\epsilon \;=\; \mathcal{O}\left(\frac{1}{\log_2 s}\left(dM\frac{s+s^{-1}}{2} + \log_2\frac{C_F}{\epsilon}\right)\right)$$

and

$$G_\epsilon = \mathcal{O}\left(\frac{C_F^2}{\epsilon^2 \log_2 s}\left(dM\frac{s+s^{-1}}{2} + \log_2\frac{C_F}{\epsilon}\right)\right)$$

neurons. In this scenario, we see that both a large band M and a large dimension d will linearly affect the first term.

Theorem 4. *Let $d \geq 2, r \in \mathbb{N}$, $f \in \mathcal{B}_{2r,2}$ and $\epsilon > 0$. There exists a deep ReLU network f^{RS} (standing for "ReLU Sobolev") with a depth of $L_\epsilon = \mathcal{O}(d^2\epsilon^{-2/r})$ and $G_\epsilon = \mathcal{O}(d^2\epsilon^{-(2+2/r)})$ neurons, such that $\left\|f^{\mathrm{RS}} - f\right\|_{L_2(B)} \leq \epsilon$.*

Proof. Let $f \in \mathcal{B}_{2r,2}$, and $M > 1$. Similar to the proof of Theorem 5, we define the bandlimiting of $f : \mathbb{R}^d \to \mathbb{R}$ by

$$f_M \;=\; \mathcal{F}^{-1}(\mathcal{F}f \mathbb{1}_{[-M,M]^d}).$$

Let us define $F : [-M, M]^d \to \mathbb{C}$:

$$F(\omega) \;=\; \frac{1}{(2\pi)^d}(\mathcal{F}f)(\omega),$$

and $K(x) = \exp(ix)$. We then have the following identity:

$$f_M(x) \;=\; \int_{[-M,M]^d} F(\omega)K(\omega \cdot x)\,\mathrm{d}\omega \;=\; \int_{[-M,M]^d} \frac{1}{(2\pi)^d}\mathcal{F}f(\omega)\exp(i\omega \cdot x)\,\mathrm{d}\omega.$$

It is easy to see that $f_M \in \mathcal{H}_{K,M}(B)$. We choose $M = (2/\epsilon)^{1/r}$. Using the same derivations as in the proof of Theorem 5, we seek to approximate f_M with a network f^{RS} ("ReLU Sobolev") such that

$$\|f_M - f^{\mathrm{RS}}\|_{L_2(B)} \;\leq\; \epsilon/2.$$

Once this is achieved, we have:

$$\begin{aligned}\|f - f^{\mathrm{RS}}\|_{L_2(B)} &\leq\; \|f - f_M\|_{L_2(B)} + \|f_M - f^{\mathrm{RS}}\|_{L_2(B)} \\ &\leq\; M^{-r} + \epsilon/2 \;\leq\; \epsilon.\end{aligned} \tag{7}$$

We consider that $C_F = \int_{[-M,M]^d} |F(\omega)|\,\mathrm{d}\omega = \frac{1}{(2\pi)^d}\int_{[-M,M]^d}|\mathcal{F}f(\omega)|\,\mathrm{d}\omega \leq 1$, where the inequality is due to the definition of $\mathcal{B}_{2r,2}$. The kernel $K(t) = \exp(it)$ takes as input $t = \omega \cdot x$, for $x \in B$ and $\omega \in [-M, M]^d$. Therefore, $t \in [-dM, dM]$, and $K : [-dM, dM] \to \mathbb{R}$. Since K is an entire function, it is continuable to E_s^{dM} for any $s > 2$, let us choose $s = 4$. We notice that $a_4^{dM} = dM(4 + 4^{-1})/2$ is the larger axis, and therefore the maximal norm of K on E_s^{dM} is given by $K(a_4^{dM})$:

$$C_K \;=\; \max_t |K(t)| \;\leq\; \exp(dM\tfrac{4+4^{-1}}{2}).$$

Further, for any $t \in \mathbb{R}$ we have $|K(t)| \leq 1 = D_K$. Using Theorem 3.2 from (Montanelli et al., 2021) we can construct a deep ReLU network f^{RS} such that

$$\|f_M - f^{\mathrm{RS}}\|_{L_2(B)} \;\leq\; \epsilon/2$$

whose depth is

$$\begin{aligned}L_\epsilon &\leq\; C_1\frac{1}{\log_2^2 4}\log_2^2\frac{2C_F C_K}{\epsilon} \\ &\leq\; C_2\frac{1}{\log_2^2 4}\left(\log_2\frac{\exp(dM\frac{4+4^{-1}}{2})}{\epsilon}\right)^2 \\ &\leq\; 12C_2\left(d\left(\frac{2}{\epsilon}\right)^{\frac{1}{r}} - \log_2\frac{1}{\epsilon}\right)^2 \\ &\leq\; C_3 d^2 \epsilon^{-\frac{2}{r}},\end{aligned} \tag{8}$$

for some constants $C_1, C_2, C_3 > 0$. In addition, the number of neurons can be bounded by

$$
\begin{aligned}
G_\epsilon &\leq C_1' C_F^2 \frac{1}{\epsilon^2 \log_2^2 4} \log_2^2 \frac{2C_K C_F}{\epsilon} \\
&\leq C_2' \frac{1}{\epsilon^2 \log_2^2 4} \left(\log_2 \frac{\exp(dM^{\frac{4+4^{-1}}{2}})}{\epsilon} \right)^2 \\
&\leq \frac{12C_2'}{\epsilon^2} \left(d \left(\frac{2}{\epsilon} \right)^{\frac{1}{r}} - \log_2 \frac{1}{\epsilon} \right)^2 \\
&\leq C_3' d^2 \epsilon^{-(2+\frac{2}{r})},
\end{aligned}
\tag{9}
$$

for some constants $C_1', C_2', C_3' > 0$. $\qquad \square$

Corollary 1. *Let $d \geq 2, r \in \mathbb{N}, f \in \mathcal{W}^{r,2}$ such that $\|\mathcal{F}f\|_{L_1(\mathbb{R}^d)} < \infty$, and $\epsilon > 0$. There exists a deep ReLU network f^{MS} (standing for "Multiplicative Sobolev") with a depth of $L_\epsilon = \mathcal{O}(\epsilon^{-1/r})$ and $G_\epsilon = \mathcal{O}(\epsilon^{-(2+(1/r))})$ neurons, such that $\|f^{\mathrm{MS}} - f\|_{L_2(B)} \leq C \max\{|f|_{r,2}^2, \|\mathcal{F}f\|_1\}\epsilon$, where $C > 0$ is a constant dependent on r, d.*

Proof. Let $f \in \mathcal{W}^{r,2}$ such that $\mathcal{F}f \in L_1(\mathbb{R}^d)$, and let $\epsilon > 0$. We define a function

$$
\tilde{f} := \frac{f}{C(r,d) \max\{|f|_{r,2}^2, \|\mathcal{F}f\|_1\}}
$$

for $C(r,d) := \sum_{\alpha:|\alpha|=r} \binom{r}{\alpha_1,\ldots,\alpha_d} \geq 1$. We will show that $\tilde{f} \in \mathcal{B}_{2r,2}$ and then by applying Theorem 5 on $\tilde{f}$ we will obtain the desired result.

By the definition of the Sobolev space, $f \in L_2(\mathbb{R}^d)$ and therefore $\tilde{f} \in L_2(\mathbb{R}^d)$. We consider $\mathcal{F}\tilde{f}$,

$$
\begin{aligned}
\frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |\mathcal{F}\tilde{f}(\omega)| d\omega &= \frac{1}{(2\pi)^d C(r,d) \max\{|f|_{r,2}^2, \|\mathcal{F}f\|_1\}} \int_{\mathbb{R}^d} |\mathcal{F}f(\omega)| d\omega \\
&= \frac{\|\mathcal{F}f\|_1}{(2\pi)^d C(r,d) \max\{|f|_{r,2}^2, \|\mathcal{F}f\|_1\}} \leq 1.
\end{aligned}
$$

We would like to show that $\frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |\omega|^{2r} |\mathcal{F}\tilde{f}(\omega)|^2 d\omega \leq 1$. Let $\omega \in \mathbb{R}^d, d \geq 2$, we have

$$
|\omega|^{2r} = \|\omega\|_{l_2}^{2r} = \left(\sum_{m=1}^d \omega_m^2 \right)^r = \sum_{\|\alpha\|_1=r} \binom{r}{\alpha_1,\ldots,\alpha_d} \cdot (\omega^\alpha)^2,
\tag{10}
$$

where $\omega^\alpha = \prod_{i=1}^d \omega_i^{\alpha_i}$ for $\alpha \in \mathbb{R}^d$. In addition,

$$
|f|_{r,2}^2 = \left(\sum_{\alpha:|\alpha|=r} \|D^\alpha f\|_2 \right)^2 \geq \sum_{\alpha:|\alpha|=r} \|D^\alpha f\|_2^2
$$

By Parseval's Identity in $\mathbb{R}^d$ (Albrecht et al., 2021):

$$
\|D^\alpha f\|_2^2 = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |\mathcal{F}(D^\alpha f)(\omega)|^2 \, d\omega = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |(\mathcal{F}f)(\omega)|^2 |\omega^\alpha|^2 \, d\omega.
$$

Hence, by (10)

$$
\begin{aligned}
\sum_{\alpha:|\alpha|=r} \|D^\alpha f\|_2^2 &= \sum_{\alpha:|\alpha|=r} \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |(\mathcal{F}f)(\omega)|^2 |\omega^\alpha|^2 \, d\omega \\
&\geq \frac{1}{(2\pi)^d \sum_{\alpha:|\alpha|=r} \binom{r}{\alpha_1,\ldots,\alpha_d}} \int_{\mathbb{R}^d} |(\mathcal{F}f)(\omega)|^2 \left(\sum_{\alpha:|\alpha|=r} \binom{r}{\alpha_1,\ldots,\alpha_d} \cdot |\omega^\alpha|^2 \right) d\omega \\
&= \frac{1}{(2\pi)^d C(r,d)} \int_{\mathbb{R}^d} |\mathcal{F}f(\omega)|^2 |\omega|^{2r} \, d\omega,
\end{aligned}
$$

where the inequality is due to an interchanging between the sum and integral, and the Cauchy-Schwartz inequality $\sum_k a_k x_k \leq (\sum_k x_k^2)^{1/2}(\sum_k a_k^2)^{1/2} \leq \sum_k x_k \sum_k a_k$ for $\{x_k\}_k, \{a_k\}_k$ positive finite series. We then arrive at the following inequality:

$$\frac{1}{(2\pi)^d C(r,d)} \int_{\mathbb{R}^d} |\omega|^{2r} |\mathcal{F}f(\omega)|^2 \ \mathrm{d}\omega \leq |f|_{r,2}^2.$$

Finally,

$$\begin{aligned}
\frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} |\omega|^{2r} |\mathcal{F}\tilde{f}(\omega)|^2 d\omega &= \frac{1}{(2\pi)^d C(r,d) \max\left\{|f|_{r,2}^2, \|\mathcal{F}f\|_1\right\}} \int_{\mathbb{R}^d} |\omega|^{2r} |\mathcal{F}f(\omega)|^2 d\omega \\
&\leq \frac{|f|_{r,2}^2}{\max\left\{|f|_{r,2}^2, \|\mathcal{F}f\|_1\right\}} \leq 1.
\end{aligned}$$
